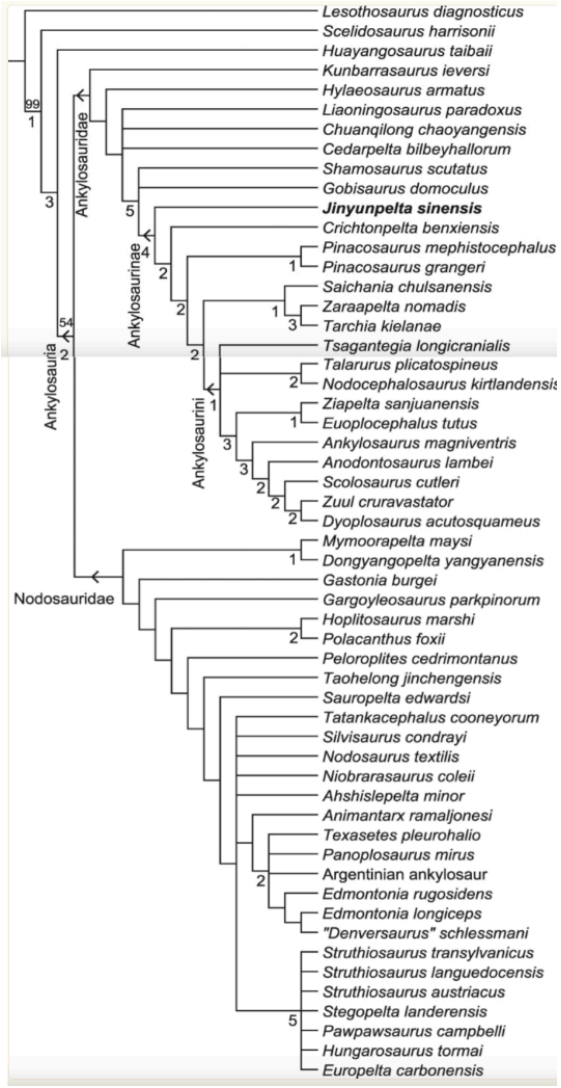
## Ankylosaurus

Ankylosaurus is a family containing Palaeoscincus (maybe we don't know if it exist or not) Crichtonsaurus bohlini and all these (graph made by Zheng)



Lets go thought them all

Crichtonpelta named after the guy who wrote jurassic park along with Crichtonsaurus bohlini

Palaeoscincus: we have some teeth bones might be unique species were not sure

Tsagantegia longicranialis: is the only species in its genus it is closely related to Pinacosaurus and Shamosaurus scutatus:only one fossil has ever been discovered with just its skull piece and part of the armor

Pinacosaurus grangeri:Pinacosaurus is possibly the most common ankylosaur genus they have a nose without the normal armor of Ankylosauridae with it being fused together
Pinacosaurus mephistocephalus: might not be a Pinacosaurus we don’t know
Heishansaurus pachycephalus:might be new genus we don’t know it's probably just an ankylosaurus its badly preserved
Zhongyuansaurus luoyangensis: just a juvenile Gobisaurus
Gobisaurus: first outgroup in Ankylosauridae discovered very similar to Shamosaurus
Ankylosaurus:The spikes ranged from 3cm-71cm in diameter (thats big)
Talarurus: a lot of misconceptions about this one like it being the only Ankylosauridae to have 4 toes: not true it having furrowed armor also false
Hylaeosaurus armatus: first ankylosaurus discovered
Animantarx ramaljonesi: on the border between 2 families
Panoplosaurus mirus: doesn’t have any promanic spikes
Zuul crurivastator the best preserved Ankylosauridae in north america was from this species it was named after a ghostbusters character
Ziapelta sanjuanensis it is the only Ankylosauridae to have flat convex and concave bones on its head
